

Introduction to Python

The following concepts shall be covered in the notebook

- Print Statements
- Variables
- Different Data-Types
- String Formatting

Printing output - We shall use a string (sequence of words) to print the sentence to the output

- We have an input cell and output cell in the notebook.
- Passing a value to the print() function shall be used to print the output to the screen
- In python, the sentences are stored in either ' quotes or " quotes
- We can use them to print the values in the following way

```
In [2]: print('Hello World')
```

```
Hello World
```

```
In [3]: print("Hello World")
```

```
Hello World
```

We have seen how the output is print using the print in-built function Now , we shall start with the basic values (Numeric/String) in python

- The numeric values that can be used in python are of three types
 - Integer
 - Float
 - Complex Type
- Integer type

```
In [4]: 22
```

```
Out[4]: 22
```

- Floting type

```
In [5]: 22.32
```

```
Out[5]: 22.32
```

- Complex Type

```
In [6]: 3+4j
```

```
Out[6]: (3+4j)
```

Let us perform some basic operations on the numbers

- Addition
- Subtraction
- Multiplication
- Division
- exponent

```
In [8]: ## Addition  
3+4
```

```
Out[8]: 7
```

```
In [9]: ## Subtraction  
8-5
```

```
Out[9]: 3
```

```
In [10]: ### Multiplication  
3*5
```

```
Out[10]: 15
```

```
In [11]: ### Division  
5/3
```

```
Out[11]: 1.6666666666666667
```

```
In [16]: ### Division with two front slashes provides the output as below -  
### it rounds off to the nearest integer.  
5//3
```

```
Out[16]: 1
```

```
In [17]: 12/2
```

```
Out[17]: 6.0
```

```
In [18]: 12//2
```

```
Out[18]: 6
```

```
In [22]: ## Exponent  
2**3
```

```
Out[22]: 8
```

```
In [23]: ## Exponent  
4**2
```

```
Out[23]: 16
```

Lets look at how to represent the string data type in Python

When we say string - It is sequence of characters.

- String are generally enclosed in single quotes or double quotes.

```
In [28]: ### Use quotes to represent the data  
         'Hello World'
```

```
Out[28]: 'Hello World'
```

```
In [29]: ### Print 'Hello World!' to console  
         print('Hello World!')  
  
Hello World!
```

```
In [25]: "Hello World!"
```

```
Out[25]: 'Hello World!'
```

```
In [30]: ### Print "Hello World!" to console  
         print("Hello World!")  
  
Hello World!
```

```
In [26]: ### Represent 'This is python' in single quotes  
         'This is python '
```

```
Out[26]: 'This is python '
```

```
In [31]: #### Print 'This is python ' in single quotes and pass it to the print function  
         print('This is python ')  
  
This is python
```

```
In [27]: #### Represent "This is Python " in double quotes  
         "This is Python"
```

```
Out[27]: 'This is Python'
```

```
In [32]: ### Print "This is Python" in double quotes and pass it to the print function  
         print("This is Python")  
  
This is Python
```

How to know which data type each value represents

- Use the type function

```
In [33]: type(20)
```

```
Out[33]: int
```

```
In [34]: type(3.14)
```

```
Out[34]: float
```

```
In [35]: type('Hello')
```

```
Out[35]: str
```

```
In [36]: type(3+3j)
```

```
Out[36]: complex
```

How to store values in Python - Use Variables

- Use of variables in python
- Python is a dynamically typed programming language
 - Dynamically Typed programming language is one where reassignment of values for different datatypes is possible

```
In [37]: # Below x is a variable and it is being assigned a integer value of 10  
x = 10
```

```
In [38]: x
```

```
Out[38]: 10
```

```
In [42]: ## check the type of x - It is of type integer.  
type(x)
```

```
Out[42]: int
```

```
In [40]: ## Y is a variable and it is being assigned a float value of 20  
y = 20.33
```

```
In [41]: y
```

```
Out[41]: 20.33
```

```
In [43]: ### Check the type of y - It is of type float  
type(y)
```

```
Out[43]: float
```

```
In [45]: ### z is a variable and it is being assigned a complex numebr of 3+2j  
z = 3 + 2j  
z
```

```
Out[45]: (3+2j)
```

```
In [47]: ### Check the type of z it is of complex type.  
type(z)
```

```
Out[47]: complex
```

```
In [50]: ### A complex number has two parts - real part and imaginary part  
### real part is got from z.real  
z.real
```

```
Out[50]: 3.0
```

```
In [51]: ### A complex number has two parts - real part and imaginary part  
### imaginary part is got from z.imag  
z.imag
```

```
Out[51]: 2.0
```

- Exercise - Compute area of triangle with given base and height

```
In [4]: ### area of trainge is given using the formula 0.5*b*h  
base = 20  
height = 15
```

```
area = 0.5 * base * height
print("Area of trinagle is ", area)
```

Area of trinagle is 150.0

Let us see how strings can be formatted

```
In [7]: ### We want to print \ within the enclosed single quotes. We can do as below
### \n stands for new line
print('hello \new world')
```

hello
ew world

- Two ways to escape the string character as mentioned below

```
In [14]: ### using the raw format of the string
print(r'hello \new world')
```

hello \new world

```
In [9]: ### If we want to escape the \ we use another \ to escape it
print('hello \\new world')
```

hello \new world

- to specify tab space in the string

```
In [10]: ## If use \t then it used as tab
print('hello \t world')
```

hello world

- Specify the apostrophe and present it as an escape character

```
In [11]: ### We want to include quote in the output of print statement. We can print the statement
print('it\'s a new world')
```

it's a new world

- Multi line statements in print statements

```
In [12]: ### Multiple line can be used in the following way - Single quote
print(''This is how first line
second line
third line are printed
''')
```

This is how first line
second line
third line are printed

```
In [13]: ### Multiple line can be used in the following way - Single quote
print("""This is how first line
second line
third line are printed
""")
```

This is how first line
second line

third line are printed

Formatting string values

- Using index values within curly braces to print the output value

```
In [21]: ### Using format function on top of the stirng value to print the output as follows  
print('Product of 2 and 3 is {}'.format(2*3))
```

Product of 2 and 3 is 6

```
In [22]: ### Let say we have more that 2 value and want to format in the string values it can be  
### as following  
print('Product of {0} and {1} is {2} '.format(2,3,2*3))
```

Product of 2 and 3 is 6

```
In [28]: ### For string values it will be denoted as following  
print('{0} {1} {2} {3}'.format("How","are","you","doing ?"))
```

How are you doing ?

- Expressing float values in print statements

```
In [26]: print('Value of pi is {}'.format(3.14))
```

Value of pi is 3.14

```
In [ ]: * Exercise using string foramtting print the area of triangle in a single line  
height = 50  
length = 10  
print() ## write code inside the print function
```

using variables in print statements

- integer and float variables in print statements

```
In [30]: x = 10  
print('Value is ' , x)
```

Value is 10

```
In [31]: ## The below throws an error  
print('value is' + x)
```

```
-----  
TypeError                                Traceback (most recent call last)  
Cell In[31], line 2  
      1 ## The below throws an error  
----> 2 print('value is' + x)  
  
TypeError: can only concatenate str (not "int") to str
```

```
In [32]: ### To correct the above statement we shall do the following  
print('Value is ' + str(x))
```

Value is 10

- We shall come back to print formatting later as we get into other data structures in python

Let us look at some other functions for integers, float and string

```
In [42]: ### Integer or float value is given - we need to convert it to string.  
### The following we can perform it  
value = 10  
str(value)
```

Out[42]: '10'

```
In [43]: fl2 = 30.5  
str(fl2)
```

Out[43]: '30.5'

```
In [49]: ### Integer/float String value is given, we need to convert that into int or float value  
str1 = '10'  
print(str1 + ' ', type(str1))  
print(str1 + ' ', int(str1), type(int(str1)))  
  
10 <class 'str'>  
10 10 <class 'int'>
```

```
In [51]: str2 = '10.54'  
print(str2 + ' ', type(str2))  
print(str2 + ' ', float(str2), type(float(str2)))  
  
10.54 <class 'str'>  
10.54 10.54 <class 'float'>
```

Python Lesson 2

In this notebook we shall cover the following aspects

- Other in-built functions
- Capture input from the command line
- Operators and Operands in Python
- divmod() function returns a pair of numbers consisting of quotient and remainder

```
In [14]: ### We pass two numbers to divmod - 5,3 : div(5,3) - It returns the quotient of the divi  
divmod(5,3)
```

Out[14]: (1, 2)

- ord() function return point value representation of a character

```
In [2]: #### Finding the unicode point value of a character 'H' - pass 'H' to the ord() function  
ord('H')
```

Out[2]: 72

```
In [3]: #### Finding the unicode point value of a character 'a' - pass 'a' to the ord() function  
ord('a')
```

Out[3]: 97

```
In [4]: #### Finding unicode point value of a character 'A' - pass 'A' to the ord() function  
ord('A')
```

Out[4]: 65

```
In [22]: ### Finding unicode point value of a character '\n'- pass '\n' to the ord() function  
ord('\n')
```

Out[22]: 10

- chr() function is the inverse of ord() - It gives the value of the give integer

```
In [21]: ### chr function that takes input as 10 would return the output as '\n'  
chr(10)
```

Out[21]: '\n'

```
In [25]: ### chr function that takes input as 97 would return the output as 'a'  
chr(97)
```

Out[25]: 'a'

```
In [26]: ### chr function that takes input as 97 would return the output as 'A'  
chr(65)
```

Out[26]: 'A'

```
In [1]: ### chr function that takes input as 8641 would return the output as '%'  
chr(8541)
```

Out[1]: '%'

- id() function gives the Cpython address location of the object

```
In [12]: ### We want to get the address of a python object - id() function provides the address o  
x = 10  
id(x)
```

Out[12]: 1455356117520

```
In [13]: #### finding the memory location address of a floating value passed to id function  
y = 20.5  
id(y)
```

Out[13]: 1455436509232

- bin() function - This will provide the binary value of the given input

```
In [28]: ### pass value 10 to the bin() function and it returns binary representation of the pass  
## The binary representation is prefixed with 0b  
bin(10)
```

Out[28]: '0b1010'

```
In [29]: ### pass value -10 to the bin() function and it returns binary representation of the pas  
## The binary representation is prefixed with -0b  
bin(-10)
```

Out[29]: '-0b1010'

- hex() function - Converts the number from string to hexadecimal representation

```
In [31]: ### pass value 10 to the hex() function and it returns the hexadecimal representation of  
## output would 0xa  
hex(10)
```

```
Out[31]: '0xa'
```

```
In [9]: ### pass value 8 to the hex() function and it returns the hexadecimal representation of  
## output would 0x8  
hex(23)
```

```
Out[9]: '0x17'
```

```
In [33]: ### pass value 17 to the hex() function and it returns the hexadecimal representation of  
## output would 0x8  
hex(17)
```

```
Out[33]: '0x11'
```

- oct function - Coverts the number from String representation to octal representation

```
In [35]: ### pass value 10 to the oct() function and it returns the octal representation of the p  
## output would 0o12 - Prefix is 0o  
oct(10)
```

```
Out[35]: '0o12'
```

```
In [36]: ### pass value 15 to the oct() function and it returns the octal representation of the p  
## output would 0o17 - Prefix is 0o  
oct(15)
```

```
Out[36]: '0o17'
```

```
In [37]: ### pass value 13 to the oct() function and it returns the octal representation of the p  
## output would 0o15 - Prefix is 0o  
oct(13)
```

```
Out[37]: '0o15'
```

- int() function - Integer values with other bases

```
In [14]: ### default base value of an integer  
int(10)
```

```
Out[14]: 10
```

```
In [16]: ### Passing a string value '10' for base 2  
int('10',base=2)
```

```
Out[16]: 2
```

```
In [17]: ### Passing a string value '10001' for base 2 - That is the representation is 10001 in b  
### This number is converted to base 10.  
int('10001',base=2)
```

Out[17]:

```
In [8]: ### Passing a string value '0xa' for base 6 - that is the representation is 0xa in base 6  
## The number is 10 in base 10  
int('0xa',base=16)
```

Out[8]: 10

```
In [5]: ### Covnverts the number from base 8 to base 10  
int('0o15', base=8)
```

Out[5]: 13

```
In [10]: ### converts the number from base 16 to base 10 - that is the representation is 0x17 in base 16  
## The number is 23 in base 10  
int('0x17',base=16)
```

Out[10]: 23

- abs() function returns the absolute value. Indicating that it returns the positive value

```
In [11]: ### pass 10.2 value to abs function - it generated the absolute value of the argument  
abs(-10)
```

Out[11]: 10

```
In [12]: ### pass 20.5 value to abs function - it generated the absolute value of the argument  
abs(-20.5)
```

Out[12]: 20.5

- pow() function returns the number for this formula - base** exponent
- base of the number and the exponent it is raised to

```
In [13]: ### pass 2 as the base followed by 3 as the exponent - 2**3 - pow(2,3)  
pow(2,3)
```

Out[13]: 8

```
In [14]: ### pass 3 as the base followed by 2 as the exponent - 3**2 - pow(3,2)  
pow(3,2)
```

Out[14]: 9

- min() function returns the minimum of two or more values

```
In [12]: ### Pass the values as -5, 10, 30 to the minimum function and check the output - min(-5, 10, 30)  
min(-5,10,30)
```

Out[12]: -5

```
In [13]: ### Pass the value as 1,2,3 to the minimum function and check the output - min(1,2,3)  
min(1,2,3)
```

Out[13]: 1

```
In [14]: ### If we pass only one value in the minimum function - then we get an error  
min(1)
```

```
-----  
TypeError                                Traceback (most recent call last)  
Cell In[14], line 1  
----> 1 min(1)  
  
TypeError: 'int' object is not iterable
```

- max() function returns the maximum of two or more values

```
In [15]: ### Pass the values as -5, 10, 30 to the maximum function and check the output - max(-5,  
max(-5,10,30)
```

```
Out[15]: 30
```

```
In [16]: ### Pass the value as 1,2,3 to the maximum function and check the output - max(1,2,3)  
max(1,2,3)
```

```
Out[16]: 3
```

- len() function gives us the length of the given string - We cannot pass integer or floating point value

```
In [5]: ### Let us pass string values to the len() function to check its length - 'Python' return  
len('Python')
```

```
Out[5]: 6
```

```
In [6]: ### Let us pass string value to len() function to check its length - 'Hello World!' return  
len('Hello World!')
```

```
Out[6]: 12
```

- repr() function gives back the printable representation of the object

```
In [11]: ### Pass 'monday' as input to repr. repr('Monday') -- The resultant output is 'Monday'  
repr('Monday')
```

```
Out[11]: "'Monday'"
```

```
In [9]: ### Pass repr('monday') as input to print. print(repr('Monday')) -- The resultant output  
print(repr('Monday'))
```

```
'Monday'
```

String Operations

- Text sequences - String
- String are sequences of text. String sequences are immutable.

```
In [16]: ### We import the string module and use ascii_letters on string. The output is english a  
### and upper case.  
import string  
string.ascii_letters
```

```
Out[16]: 'abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ'
```

```

In [17]: ### The ascii_lowercase shall return the lower case letters on string. The output is eng
         string.ascii_lowercase

Out[17]: 'abcdefghijklmnopqrstuvwxyz'

In [18]: #### the ascii_uppercase shall return the upper case letters as string. the output is e
         string.ascii_uppercase

Out[18]: 'ABCDEFGHIJKLMNOPQRSTUVWXYZ'

In [19]: #### The digits shall return the digits as string. The ouput is '0123456789'
         string.digits

Out[19]: '0123456789'

In [20]: #### The digits shall return hexadecimal digits as string . The output is '0123456789abc
         string.hexdigits

Out[20]: '0123456789abcdefABCDEF'

In [21]: #### The digits shall return octal digits as string. The output is '01234567'
         string.octdigits

Out[21]: '01234567'

In [22]: #### The digits shall return punctutation marks as string. The output is '!"#$%&\'()*+,-
         string.punctuation

Out[22]: '!"#$%&\'()*+,-./:;<=>?@[\\]^_`{|}~'

```

- The Stiring value can be stored in three ways
 - In single quotes
 - In double quotes
 - In triple quotes

```

In [2]: ### Textutal data can be put in single quotes. for example text_s_quote = 'Tuticorn has
         text_s_quote = 'Tuticorn has two words tuti and corn'
         text_s_quote

Out[2]: 'Tuticorn has two words tuti and corn'

In [4]: #### Textual data can be put in double quotes. For Example text_d_Quote = "Tuticorn has
         text_d_Quote = "Tuticorn has two words tuti and corn"
         text_d_Quote

Out[4]: 'Tuticorn has two words tuti and corn'

In [9]: #### Textual data can be put in triple quotes It can be multiple line also. For exampe t
         text_tr_Quote = """
         Tuticorn has
         two words - tuti
         and corn
         """
         text_tr_Quote

Out[9]: '\nTuticorn has\ntwo words - tuti\nand corn\n'

```

- Accessing the string values based on indices - [:] index start from zero

|P|R|B|H|A|S|

=====

|0|1 |2 |3 |4|5|

```
In [10]: #####|T|u|t|i|c|o|r|n| |h|a |s | | |t| w| o| | w| o |r |d |s |22 | t| u| t| i | | a |
#####|0|1|2|3|4|5|6|7|8|9|10|11|12|13|14|15|16|17|18|19|20|21|22 |23|24|25| 26|27|28|29
### String values can be accessed using index operators. text_data = "Tuticorn has two w
### text_data[0:5]
text_data = "Tuticorn has two words tuti and corn"
text_data[0:5]
```

Out[10]: 'Tutic'

```
In [15]: ### If string value are provided as [start:] where start=0 or [:] , then entire string w
#####|T|u|t|i|c|o|r|n| |h|a |s | | |t| w| o| | w| o |r |d |s |22 | t| u| t| i | | a |
#####|0|1|2|3|4|5|6|7|8|9|10|11|12|13|14|15|16|17|18|19|20|21|22 |23|24|25| 26|27|28|29
text_data = "Tuticorn has two words tuti and corn"
text_data[0:]
```

Out[15]: 'Tuticorn has two words tuti and corn'

```
In [13]: ### If string values are provided as [start:end] where start is some number and
##### end is some number less than length of the string. Then it slices only that many end
#####|T|u|t|i|c|o|r|n| |h|a |s | | |t| w| o| | w| o |r |d |s |22 | t| u| t| i | | a |
#####|0|1|2|3|4|5|6|7|8|9|10|11|12|13|14|15|16|17|18|19|20|21|22 |23|24|25| 26|27|28|29
start = 3
end = 15
text_data[start:end]
```

Out[13]: 'icorn has tw'

- String methods
 - capitalize()
 - count()
 - endswith
- captalize() - This method on string returns a copy by making the first character of the string in uppercase and the reset lowercased

```
In [18]: ### "tuticorn".capitalize() shall return the output as Tuticorn
"tuticorn".capitalize()
```

Out[18]: 'Tuticorn'

- count() - This method counts the number of times a given sub-string occurs in a given string

```
In [19]: ### "Tuticorn has two words tuti and corn".count('corn') counts the number of time corn
"Tuticorn has two words tuti and corn".count('corn')
```

Out[19]: 2

- `center()` - Centres the string with the necessary padding at the ends

```
In [30]: ### "Tuticorn" centers the string with the necessary padding at the ends.
print("tuticorn".center(12))
"tuticorn".center(12, "=")
```

```
tuticorn
Out[30]: '==tuticorn=='
```

- `endswith()` returns true if the string is available as suffix at the end.

```
In [33]: ### "Tuticorn has two words tuti and corn".endswith("corn") shall return True
"tuticorn has two words tuti and corn".endswith("corn")
```

```
True
Out[33]:
```

- `in` operator can also be used to check if a sub-string is available in String

```
In [37]: ### "corn" in "Tuticorn has two words tuti and corn" returns True
"corn" in "Tuticorn has two words tuti and corn"
```

```
True
Out[37]:
```

```
In [39]: ### "corns" in "Tuticorn has two words tuti and corn" returns False
"corns" in "Tuticorn has two words tuti and corn"
```

```
False
Out[39]:
```

- `format` on string can be used for formatting the string. The string on which this method is called can contain literal text or replacement fields delimited by braces `{}`

```
In [45]: ### Passing the value without any index
### "corn can be good during a {}".format("movie") {} is replaced with movie
"corn can be good during a {}".format("movie")
```

```
'corn can be good during a movie'
Out[45]:
```

```
In [46]: #### Index can be also be used to replace the positional argument with the string value
#### "value of two numbers {0} and {1} is {2} ".format(4,5,9)
"value of two numbers {0} and {1} is {2} ".format(4,5,9)
```

```
'value of two numbers 4 and 5 is 9 '
Out[46]:
```

- `find()` - find function finds the index of the substring in the string
If the substring is not found -1 will be returned

```
In [50]: #### corn function finds it at the index
## print("Tuticorn has two words tuti and corn".find("corn")) at 4
print("Tuticorn has two words tuti and corn".find("corn"))
print("Tuticorn has two words tuti and corn".find("has",15,36))
```

```
4
-1
```

- `isalpha()` - Returns True if all characters in the string are alphabetic and there is at least one character, False otherwise

```
In [54]: ##### "234".isalpha() returns True, "helloworld".isalpha() returns True
print("234".isalpha())
print("helloworld".isalpha())

False
True
```

- `isdecimal()` returns True, if the value is decimal (0-9) else it returns false.

```
In [63]: ##### "10.23".isdecimal() returns False "234".isdecimal() returns False, "\u00B3".isdecimal() returns False
print("10.23".isdecimal())
print("234".isdecimal())
print("\u00B3".isdecimal())

False
True
False
```

- `isdigit()` returns true if all characters are digits and at least one character. Else it returns False. Unicode representations are also considered as digits

```
In [60]: ##### "121".isdigit() returns True, "A123".isdigit() returns False, "\u00B3".isdigit() returns False
print("121".isdigit())
print("A123".isdigit())
print("\u00B3".isdigit())

True
False
True
```

- `islower()` returns true if the case of all characters is lowercase. Else False otherwise

```
In [62]: ### "tuticorn has two words tuti and corn".islower() returns True. "TUTICORN has two words tuti and corn".islower() returns False
print("tuticorn has two words tuti and corn".islower())
print("TUTICORN has two words tuti and corn".islower())

True
False
```

- `isupper()` returns True if the case of all the characters is uppercase. Else False otherwise

```
In [77]: ### "TUTICORN HAS TWO WORDS TUTI AND CORN".isupper() returns True. "TUTICORN has two words tuti and corn".isupper() returns False
print("TUTICORN HAS TWO WORDS TUTI AND CORN".isupper())
print("TUTICORN has two words tuti and corn".isupper())

True
False
```

- `strip()` function returns the copy of the string with the leading characters removed.

```
In [78]: ##### strip() function removes the spaces around the string. " TUTICORN ".strip() removes spaces
print(" TUTICORN ".strip())

TUTICORN
```

- title() function returns the string with the first letter in each word is capitalized.

```
In [81]: ### title() function returns the capitalized word. "tuti corn".title() returns Tuti Corn
print("tuti corn".title())
```

Tuti Corn

Capturing Input from Command line using the input() function

```
In [92]: ### Pass name as input to capture the input from the command line
print(f'My name is', end=' ')
name = input()
```

My name is Jayant

```
In [93]: ### pass age as input to capture the input from the command line
print('Age is',end=' ')
age = input()
print(type(age))
```

Age is 5
<class 'str'>

```
In [95]: ### pass price value as input to capture the input from the command line
print('Price is' , end=' ')
price = input()
price = float(price)
print(type(price))
```

Price is 20.0
<class 'float'>

```
In [96]: ### Exercise - Capture three inputs from the command line - name, address and mobile and
### details to the screen.
```

```
In [99]: name = input('Enter your name ')
address = input('Enter your address ')
mobile = input('Enter your mobile number')
print("name of the person is {}, address is {}, Mobile numer is {}".format(name,address,mobile))
```

Enter your namejayant
Enter your addressIndia
Enter your mobile number9776975664
name of the person is jayant, address is India, Mobile numer is 9776975664

Operators and Operands in python

- Arithmetic Operators
- Comprision Operators
- Boolean Operators
- Bitwise Operators
- Identity Operators
- Membership Operators

- Arithmetic Operators
 - Addition
 - Subtraction
 - Multiplication
 - Division

- Modulo
- exponential

- Addition - Adds two numbers ('+')

```
In [102... ### Add two number using '+'  
x = 10  
y = 13  
print(x+y)
```

23

- Subtraction - Subtract two numbers ('-')

```
In [103... #### Subtract two number using '-'  
x = 13  
y = 10  
print(x-y)
```

3

- Multiplication - multiply two numbers ('*')

```
In [104... #### Multiply two numbers using '*'  
x = 10  
y = 5  
print(x*y)
```

50

- Division - Division of two number ('/') or ('//')

```
In [105... #### Divide two numbers using '/'  
x = 15  
y = 10  
print(x/y)  
print(x//y)
```

1.5

1

- Modulo - Modulo of two numbers (%)

```
In [106... #### Find the remainder of two numbers using %  
x = 20  
y = 10  
print(x%y)
```

0

```
In [107... #### Find the remainder of two numbers using %  
x = 30  
y = 4  
print(x%y)
```

2

- Exponential - exponent of two numbers (**)

In [109... *#### Find the exponent of a number - Base and exponent*

```
x = 2  
y = 3  
print(2**3)
```

8

- Comprision Operators
 - Less than(<)
 - greater than (>)
 - less than or equal to (<=)
 - equal to (==)
 - greater than or equal to (>=)
 - Not equal to (!=)

In [110... `5 < 3`

Out[110]: False

In [111... `9 > 4`

Out[111]: True

In [112... `10 >= 10`

Out[112]: True

In [113... `11 >= 15`

Out[113]: False

In [114... `13 <= 14`

Out[114]: True

In [115... `12 == 14`

Out[115]: False

In [116... `15 == 16`

Out[116]: False

In [117... `12 == 12`

Out[117]: True

In [118... `23 != 24`

Out[118]: True

In [119... `23 != 23`

Out[119]: False

- Boolean Operators
 - and
 - or
 - not

```
In [121... ### Perform the operation as below for 'and' operator- Check (x > y) and (y > z) for ou
x = 5
y = 2
z = 3
(x>y) and (y>z)
```

Out[121]: False

```
In [122... #### Perform the operation as below for 'or' operator- Check (x > y) or (y > z) for out
x > y or z > y
```

Out[122]: True

```
In [123... #### Perform the operation as below for not operator - Check x != y
print(x!=y)
```

True

- Bitwise Operators

```
In [128... #### Bitwise opearators AND (0&1 gives 0, 1&0 give 0, 1&1 give 1,0&0 gives 0)
print(0&1)
```

0

```
In [127... print(0&0)
```

0

```
In [129... print(1&1)
```

1

```
In [130... print(1&0)
```

0

Python-Lesson 03

In this notebook, we shall cover the following concepts

- Bitwise operators
- Membership operators
- Identity Operators
- Conditional Statements
- Python Data Structures
 - List
 - Tuple
 - Sets
 - Dictionary
 - Collections in Python

- Bitwise Operators
- Membership Operators
- Identity Operators

- Bitwise Operators
- Bitwise AND (&) Operator

```
In [6]: print(bin(3))
print(bin(5)) # 011 & 101 --> 1
```

```
0b11
0b101
```

```
In [7]: 3&5
```

```
Out[7]: 1
```

- Bitwise OR (|) Operator

```
In [ ]: # 0011 | 0101 -> 0111
```

```
In [9]: print(3|5)
```

```
7
```

- Bitwise XOR (^) Operator

```
In [1]: # 1011 ^ 1100 -> 0111 (11^12 -> 7)
print(11^12)
```

```
7
```

- Bitwise << left shift operator - The left shift operator shifts the left bits operand towards left.
- 1100 << 2 means that the two zeros are appended at the right side. 110000 is the output

```
In [14]: ### input is 1100 --> 12 << 2 output is 110000 (48) is the output
12 << 2
```

```
Out[14]: 48
```

- Bitwise >> right shift operator - The right shift operator shifts the right side bits. The right side bits are removed.
- 110011 >> 2 means that the last two bits are removed from the right side. 1100 is the output.

```
In [21]: # 51 -> in binary is 110011 and when last two are removed we get 1100 (12) as the output
51 >> 2
```

```
Out[21]: 12
```

- Bitwise one's complement operator (~) x -> -(x+1) . This gives the complement of the binary number
- ~10 (1010) -> -11

In [22]: `~10`

Out[22]: -11

In [24]: `~-10`

Out[24]: 9

In [26]: `#### Exercise - check if a number is even using bitwise & operator`
`x = 11`
`x&1 == 1 # odd number`

Out[26]: True

In [28]: `y = 12`
`y&1 == 0 # even number`

Out[28]: True

- Membership Operators - in and not in

In [35]: `### We can check the if the values are available or not in the given string for operator`
`## a='hello' in b='hello can i know the time please ?' check a in b`
`a = 'hello'`
`b = 'hello can i know the time please ?'`
`a in b`

Out[35]: True

In [33]: `### We can check the if the values are available or not in the given string for operator`
`## a='bell' in b='hello can i know the time please ?' check a not in b`
`a = 'bell'`
`b = 'hello can i know the time please ?'`
`a not in b`

Out[33]: True

In [34]: `### We can check the if the values are available or not in the given string for operator`
`## a='bell' in b='hello can i know the time please ?' check a in b`
`a = 'bell'`
`b = 'hello can i know the time please ?'`
`a in b`

Out[34]: False

- Identity Operators - is and is not

In [36]: `### is or is not operators can be used to know if certain conditions are met are not`
`a = 21`
`b = 33`
`c = b`
`print(c is b)`

Out[36]: True

```
In [37]: print(c is not b)
```

False

Python Conditional Statements

if expr: </br> statement </br> elif expr: </br> statement </br> elif expr: </br> statement </br> elif expr: </br> statement </br> : </br> : </br> : </br> else:
statement

```
In [58]: ## Simple condition for two numbers
x = 10
y = 20
if y > x:
    print('Y is greater')
else:
    print('X is greater')
```

Y is greater

```
In [43]: ### Enter a name to Capture input from the command line and write conditions for it.
name = input('Enter name ')
if name == 'Jayant' :
    print('Please start')
elif name == 'Vamshi':
    print('Please turn around')
elif name == 'Mayank':
    print('Please be seated')
else:
    print('Not in the name')
```

Enter name Hari

Not in the name

```
In [45]: ### Writing a if else block of code to capture the statements such that
## we print statements only for age group of 13
age = input('Enter age of participant')
age = int(age)
if age >= 13:
    print('You can start coding')
else:
    print('Please learn basics of scartch')
```

Enter age of participant15

You can start coding

Hacker Rank Questions

Hacker Rank Question Given an integer, perform the following conditional actions: If n is odd, print Weird If n is even and in the inclusive range of 2 to 5, print Not Weird If n is even and in the inclusive range of 6 to 20, print Weird If n is even and greater than 20 , print Not Weird n >= 1 and n <= 100

```
In [57]:
```

Enter a number 1 to 100 4

Not weird

```
In [ ]:
```

```
In [ ]:
```

```
In [ ]: ## Summary of above n --> weird ( odd , even and 6 to 20) Not weird (even and 2to 5 and
n = input('Enter a number 1 to 100 ')
```

```

n = int(n)
if n % 2 != 0 and n <= 20:
    print('Weird')
elif n%2 == 0 and 2<=n <= 5:
    print('Not weird')
elif n%2 == 0 and 6<=n<=20:
    print('Weird')
else:
    print('Not weird')

```

Loops in Python

- while loop in python

In []:

```

In [35]: ### while loops in python
x = 0
while x < 7:
    print(x)
    x += 1

Python Data Structures

- List
- Tuple
- Sets
- Dictionary
- Collections in Python

- List - List of comma separated values (items) between square brackets </br>
 - Lists can be heterogenous - can take different values. </br>
 - Lists can be accessed based on indices. </br>

</br> | 0 | 1 | 2 | 3 | 4 | </br> | 1 | 2 | 3 | 4 | 5 | </br> | -5 | -4 | -3 | -2 | -1 | </br>

```
In [10]: ### Creating an empty list - []
numval = []
```

```
In [1]: numbers = [1,2,3,4,5]
numbers
```

```
Out[1]: [1, 2, 3, 4, 5]
```

```
In [2]: #### finding the numbers with zeroth index - numbers[0]
numbers[0]
```

```
Out[2]: 1
```

```
In [4]: #### Finding the numbers from the last - numbers[-1]
numbers[-1]
```

```
Out[4]: 5
```

```
In [5]: #### finding the number from first (0) to last- numbers[0:]
numbers[0:]
```

```
Out[5]: [1, 2, 3, 4, 5]
```

```
In [6]: ##### finding the numbers from first index (1) to (4) index - numbers[1:4]
numbers[1:4]
```

```
Out[6]: [2, 3, 4]
```

```
In [7]: ##### finding the numbers from second index (2) to (5) index - numbers[2:5]
numbers[2:5]
```

```
Out[7]: [3, 4, 5]
```

```
In [8]: ##### finding the numbers from last index -3 to to the zeroth index -numbers[-3:]
numbers[-3:]
```

```
Out[8]: [3, 4, 5]
```

- Print all numbers

```
In [9]: ### listing all the numbers from the list - numbers[:]
numbers[:]
```

```
Out[9]: [1, 2, 3, 4, 5]
```

- print length of numbers

```
In [11]: ### length of the list can be found using - len(numbers)
len(numbers)
```

```
Out[11]: 5
```

- Assign value to particular index

```
In [14]: ##### We can reassign value to a index in a list - assign a new number to index 0
numbers[0] = 11
```

```
In [15]: numbers
```

```
Out[15]: [11, 2, 3, 4, 5]
```

- append() elements to a list

```
In [16]: ##### List values can be appended at the end in a list - numbers.append() - numbers.append
```

```
In [17]: ##### List of number after the append - numbers
```

```
Out[17]: [11, 2, 3, 4, 5, 6]
```

- To check the type of the list

```
In [18]: ##### Check type of list
type(numbers)
```

```
Out[18]: list
```

- Elements of list is heterogenous

```
In [19]: ##### Different types of values an be appended to a list
listValues = ['Apple', 'Banana', 23, 24, 25, 26]
listValues
```

```
Out[19]: ['Apple', 'Banana', 23, 24, 25, 26]
```

- Append elements to a list using append()

```
In [20]: ##### List can also be appended with 'Mango' at the list
listValues.append('Mango')
```

```
In [21]: ##### list value can also be appended with [33,45,56]
listValues.append([33,45,56])
```

```
In [22]: listValues
```

```
Out[22]: ['Apple', 'Banana', 23, 24, 25, 26, 'Mango', [33, 45, 56]]
```

- Create list using the timing values - ['1:30','2:30','3:30','4:30','5:30','6:30','7:30']

```
In [30]: ### timings values are like this - timings = ['1:30','2:30','3:30','4:30','5:30','6:30',
timings = ['1:30','2:30','3:30','4:30','5:30','6:30','7:30']
timings[0:3]
```

```
Out[30]: ['1:30', '2:30', '3:30']
```

```
In [31]: ## Slice the list value from 2:5
timings[2:5]
```

```
Out[31]: ['3:30', '4:30', '5:30']
```

```
In [32]: ## Slice the list value from 4:
timings[4:]
```

```
Out[32]: ['5:30', '6:30', '7:30']
```

- reverse() a list

```
In [33]: ### To find the reverse of the list - list[::-1]
timings[::-1]
```

```
Out[33]: ['7:30', '6:30', '5:30', '4:30', '3:30', '2:30', '1:30']
```

```
In [46]: ### Alternatively to reverse the list- use the timings.reverse()
timings.reverse()
timings
```

```
Out[46]: ['1:30', '2:30', '3:30', '4:30', '5:30', '6:30', '7:30']
```

- index of a value in the list

```
In [47]: #####To get the index of the given element - timings.index('2:30')
timings.index('2:30')
```

Out[47]: 1

- insert an element at a particular index

```
In [49]: ### Insert the value 8 at the index 2 - timings.insert(2,8)
```

```
In [50]:
```

```
Out[50]: ['1:30', '2:30', 8, '3:30', '4:30', '5:30', '6:30', '7:30']
```

- remove a value from the list

```
In [51]: ### To remove an element from the list we can do this - timings  
timings.remove(8)  
timings
```

```
Out[51]: ['1:30', '2:30', '3:30', '4:30', '5:30', '6:30', '7:30']
```

- pop an element from the list

```
In [52]: ### to remove the top most element from the list - timings - timings.pop()  
timings.pop()
```

```
Out[52]: '7:30'
```

- sort() an element from the list

```
In [56]: ### using the sort() list can be sorted - timings.sort()  
timings.sort()
```

```
In [57]: timings
```

```
Out[57]: ['1:30', '2:30', '3:30', '4:30', '5:30', '6:30']
```

- extend an element from the list

```
In [58]: ## Extend the list by adding the elements - Elements shall be appended at the end of the  
## extend - ['7:30','8:30','9:30']  
timings.extend(['7:30','8:30','9:30'])
```

```
In [59]: timings
```

```
Out[59]: ['1:30', '2:30', '3:30', '4:30', '5:30', '6:30', '7:30', '8:30', '9:30']
```

- Iterate a list

```
In [61]: for timing in timings:  
    print("The time now is {}".format(timing))
```

```
The time now is 1:30  
The time now is 2:30  
The time now is 3:30  
The time now is 4:30
```

```
The time now is 5:30
The time now is 6:30
The time now is 7:30
The time now is 8:30
The time now is 9:30
```

- sum of elements in a list

```
In [3]: ### Lets build a list using 10,11,12,13,14,15,16 - The sum of all the elements in the li
### in two ways - sum(intList) or using for loops

print('Sum of the list of elements',sum(intList))
print(intList)

Sum of the list of elements 91
[10, 11, 12, 13, 14, 15, 16]
```

- sum of the elements using for loops

```
In [4]: intList = 10,11,12,13,14,15,16
slist = 0
for i in intList:
    slist += i
print(slist)

91
```

- for comprehensions

For comprehension is a simple way of returning the value based on certain input

```
In [62]: ## Based on the range object lets find the square of each number
y = [x**2 for x in range(5)]
```

```
In [63]: y
```

```
Out[63]: [0, 1, 4, 9, 16]
```

```
In [65]: ## We can also include condition within the for comprehension
y = [x**2 for x in range(10) if x%2 == 0 ]
print(y)

[0, 4, 16, 36, 64]
```

```
In [66]: ### return if only list contains letters starting with s
names = ['sunday','super','semi-conductor','non-conductor','mango','apple']
y = [x for x in names if x.startswith('s')]
```

```
In [67]: y
```

```
Out[67]: ['sunday', 'super', 'semi-conductor']
```

Tuples

- Tuples are immutable objects that can be represented in ()
- Tuples can be accessed using indices
- Tuples are created by passing vlues to ()

```
In [76]: tup1 = (25, 'Mango', 'Rajesh', 40, 25, 24, 25)
tup1[1]
```

```
Out[76]: 'Mango'
```

```
In [77]: tup1[3]
```

```
Out[77]: 40
```

```
In [78]: ### Tuples can be iterated over using for loop
for x in tup1:
    print(x)
```

```
25
Mango
Rajesh
40
25
24
25
```

```
In [75]: ## Assigning a value to tuple shows error - tuple object does not support assignment
tup1[0] = 35
```

```
-----

Cell In[75], line 2
      1 ## Assigning a value to tuple shows error - tuple object does not support assignment
----> 2 tup1[0] = 35

TypeError: 'tuple' object does not support item assignment
```

```
In [79]: ## Count function gives the count of the element in the tuple
tup1.count(25)
```

```
Out[79]: 3
```

```
In [68]: ### Exercise - There are two list [2,3,4] and [2,5,6] -Get a combination (x,y)
## x is the element from first list,
## y is the element from second list - Get combinations (x,y) such that x is not equal to y

x = [2,3,4]
y = [2,5,6]
output = [(a,b) for a in x for b in y if x!=y]
print(output)
```

```
[(2, 2), (2, 5), (2, 6), (3, 2), (3, 5), (3, 6), (4, 2), (4, 5), (4, 6)]
```

• Sets in Python

- Sets contain unique elements
- Sets are unordered sequence of elements
- They are represented using the {} (curly braces)

```
In [80]: elements = {'Mahesh', 'Mahesh', 'Suraj', 'Ravi', 'Kiran', 'Surya'}
elements
```

```
Out[80]: {'Kiran', 'Mahesh', 'Ravi', 'Suraj', 'Surya'}
```

```
In [6]: #### Sets can be constructed using the following set keyword and passing a list to it
eles = set(['Mahesh', 'Mahesh', 'Suraj', 'Ravi', 'Kiran', 'Surya'])
```

```
els
```

```
Out[6]: {'Kiran', 'Mahesh', 'Ravi', 'Suraj', 'Surya'}
```

- Iteration over sets in python

```
In [83]: elements
```

```
Out[83]: {'Kiran', 'Mahesh', 'Ravi', 'Suraj', 'Surya'}
```

```
In [84]: for x in elements:  
         print(x)
```

```
Suraj  
Surya  
Ravi  
Mahesh  
Kiran
```

```
In [86]: ## The set elements are given below - We can represent the data as els = {'Mahesh','Mahe  
els = {'Mahesh','Mahesh','Suraj','Ravi','Kiran','Surya'}  
len(els)
```

```
Out[86]: 5
```

- Adding elements to set

```
In [87]: ### Add the following element to the set elements 'Mitra' using add function  
els.add('Mitra')
```

```
In [88]: els
```

```
Out[88]: {'Kiran', 'Mahesh', 'Mitra', 'Ravi', 'Suraj', 'Surya'}
```

```
In [91]: ## Lets create one more set els2 = els2 = {'kiran','Mahesh', 'Mitra'}  
els2 = {'kiran','Mahesh', 'Mitra'}
```

- seta.difference(setb) - Difference gives the elements that are in seta

```
In [2]: els.difference(els2)
```

```
-----  
NameError                                Traceback (most recent call last)  
Cell In[2], line 1  
----> 1 els.difference(els2)  
NameError: name 'els' is not defined
```

- difference_update() - Removes the elements from the other set

```
In [98]: els.difference_update(els2)
```

```
In [99]: els
```

```
Out[99]: {'Kiran', 'Ravi', 'Suraj', 'Surya'}
```

```
els2
```

In [100]:

Out[100]: {'Mahesh', 'Mitra', 'kiran'}

In [101]:

```
## Create the set and try to perform union on els and els2
els = {'Mahesh', 'Mahesh', 'Suraj', 'Ravi', 'Kiran', 'Surya'}
len(els)
```

Out[101]: 5

- union combines both the sets with unique elements

In [103]:

```
els.union(els2)
```

Out[103]: {'Kiran', 'Mahesh', 'Mitra', 'Ravi', 'Suraj', 'Surya', 'kiran'}

- intersection provides the common elements between the sets

In [105]:

```
els.intersection(els2)
```

Out[105]: {'Mahesh'}

In [106]:

```
print(els)
print(els2)

{'Suraj', 'Surya', 'Ravi', 'Mahesh', 'Kiran'}
{'Mitra', 'Mahesh', 'kiran'}
```

- Symmetric difference gives the elements that are not common as one single set.

In [108]:

```
## els.symmetric_difference(els2) gives the common elements between both the sets.
els.symmetric_difference(els2)
```

Out[108]: {'Kiran', 'Mitra', 'Ravi', 'Suraj', 'Surya', 'kiran'}

- Comprehension for set - Similar to for comprehension for Set
 - return type is Set when set comprehension is performed

In [8]:

```
listVal = {'Mahesh', 'Mahesh', 'Suraj', 'Ravi', 'Kiran', 'Surya'}
uniEle = {x for x in listVal}
uniEle
```

Out[8]: {'Kiran', 'Mahesh', 'Ravi', 'Suraj', 'Surya'}

- **Dictionary in Python** - Dictionaries in Python are basically key,value pairs.
 - In a dictionary, key can be any unique object
 - Keys are unique and non-duplicated
 - Values can be duplicated
 - Dictionaries can be constructed using the dict() or {}
- Create Dictionary using the dict() keyword

In [13]:

```
idName = dict()
```

```
idName[101] = 'Suraj'  
idName[102] = 'Mahesh'  
idName[103] = 'Surya'  
idName[104] = 'Ravi'  
idName[105] = 'Kiran'  
idName[106] = 'Mitra'  
idName
```

```
Out[13]: {101: 'Suraj',  
          102: 'Mahesh',  
          103: 'Surya',  
          104: 'Ravi',  
          105: 'Kiran',  
          106: 'Mitra'}
```

```
In [37]: ### Another way of creating the dictionary is the following  
idName = {101: 'Suraj', 102: 'Mahesh', 103: 'Surya', 104: 'Ravi', 105: 'Kiran', 106: 'Mitra'}  
idName
```

```
Out[37]: {101: 'Suraj',  
          102: 'Mahesh',  
          103: 'Surya',  
          104: 'Ravi',  
          105: 'Kiran',  
          106: 'Mitra'}
```

- Retrieve the value of dictionary using key

```
In [17]: ### The dictionary name and the id can be passed to get the value - idName[101]
```

- Check if the key is in the dictionary

```
In [21]: ### Check if a particular key is available in the dictionary - 101 in idName  
101 in idName
```

```
Out[21]: True
```

```
In [24]: ### Check if a particular key is not available in the dictionary - 109 not in idName  
print(109 not in idName)  
print(110 in idName)
```

```
True  
False
```

- iterate over the dictionary using keys()

```
In [34]: ### We can iterate over the dictionary using the keys() function on the dictionary.  
for k in idName.keys():  
    print(f'Key is {k}')
```

```
Key is 101  
Key is 102  
Key is 103  
Key is 104  
Key is 105  
Key is 106
```

- Values for the dictionary using values()

```
In [36]: for v in idName.values():
```

```
print(f'value is {v}')
```

```
value is Suraj  
value is Mahesh  
value is Surya  
value is Ravi  
value is Kiran  
value is Mitra
```

- iterate over a dictionary using items()

```
In [33]: for key,value in idName.items():  
        print(f'Id is {key}, Name is {value}')
```

```
Id is 101, Name is Suraj  
Id is 102, Name is Mahesh  
Id is 103, Name is Surya  
Id is 104, Name is Ravi  
Id is 105, Name is Kiran  
Id is 106, Name is Mitra
```

- Iterate over a dictionary using the dictionary object

```
In [39]: ### Using the dictionary object only the dictionary is used  
for keyVal in idName:  
    print(keyVal)
```

```
101  
102  
103  
104  
105  
106
```

- Delete a key in the dictionary using the del keyword

```
In [40]: ## Delete the key value pair using the idName[key]  
del idName[101]
```

```
In [41]: idName
```

```
Out[41]: {102: 'Mahesh', 103: 'Surya', 104: 'Ravi', 105: 'Kiran', 106: 'Mitra'}
```

- To get a value from the dictionary using the get() function or the []

```
In [42]: idName[102]
```

```
Out[42]: 'Mahesh'
```

```
In [43]: idName.get(102)
```

```
Out[43]: 'Mahesh'
```

- If the key is not in the dictionary using the get() method we can use the default value

```
In [49]: ### Lets say we dont have the key/value pair in the dictionary it returns a key error  
idName[109]
```

```
KeyError                                Traceback (most recent call last)
Cell In[49], line 2
      1 ### Lets say we dont have the key/value pair in the dictionary
----> 2 idName[109]

KeyError: 109
```

```
In [51]: # If the key is available then it returns the value
        idName.get(102,"Value is Not there")
```

```
Out[51]: 'Mahesh'
```

```
In [46]: idName.get(109,"Key/Value is Not there")
```

```
Out[46]: 'Key/Value is Not there'
```

```
In [55]: ### To get the keys in the reversed order we can use reversed on the dictionary
```

```
In [54]: for i in reversed(idName):
        print(i)
```

```
106
105
104
103
102
```

```
In [58]: ## Collecting the dictionary keys as list - list(idName)
        list(idName)
```

```
Out[58]: [102, 103, 104, 105, 106]
```

- To remove one key,value pair from the dictionary - using popitem()

```
In [59]: ## idName.popitem() will remove one key value pair from the dictionary
        idName.popitem()
```

```
Out[59]: (106, 'Mitra')
```

- To remove one key at a time from the dictionary - using pop()

```
In [64]: ### ## idName.pop(key) will pop one key value pair for the given key from the dictionary
        idName.pop(104)
```

```
Out[64]: 'Ravi'
```

```
In [65]: ### If the key is not available in the dictionary, pop() shall given an error on the dic
        idName.pop(105)
```

```
-----
KeyError                                Traceback (most recent call last)
Cell In[65], line 2
      1 ### If the key is not available in the dictionary, pop() shall given an error on
        the dictionary
----> 2 idName.pop(105)

KeyError: 105
```

- length of the dictionary - len() function

```
In [67]: # To get the length of the dictionary
len(idName)
```

```
Out[67]: 2
```

- Lets say we want to get the key,value pairs using the dictionary using dictionary comprehension

```
In [71]: ### Dictionary comprehension can be performed using the following:
idName = idName = {101: 'Suraj',102: 'Mahesh',103: 'Surya', 104: 'Ravi', 105: 'Kiran', 106: 'Mitra'}

# get only the even ids

evenIdName = {k:v for (k,v) in idName.items() if k%2 ==0 }
evenIdName
```

```
Out[71]: {102: 'Mahesh', 104: 'Ravi', 106: 'Mitra'}
```

Range Function - range()

- Range Function is a built function
- Range function can be used for creating sequence of integer values
- The Range function can be iterated over
- It can also be used to create other data structures like List and Tuples

```
In [1]: range(10)
```

```
Out[1]: range(0, 10)
```

- Range function can be iterated using the for loop
- In the code below, we shall user the 'for' keyword and the 'in' keyword and iterate over the range by passing a value. Alos please note that within the 'print' function we can use the 'end' to iterate over the value

```
In [3]: # Example - Iterating over the range function
for i in range(10):
    print(i, end=' ') # Here, in the print function we can use the end as the
                    #separator to print the output in one single line

0 1 2 3 4 5 6 7 8 9
```

- Range function has other paramenters - we can understand the parameters as something below :
startIndex, endIndex and stepSize </br> Let us look at an example below - </br> The start value/index is given as 2 </br> The end value/index is given as 10 </br> the step/value index is given as 5 </br>

```
In [2]: # start - 4
# end - 18
# step - 2

rng1 = range(4,18,2) # Every alternate number would be printed with the difference in th
for i in rng1:
    print(i , end=' ')

4 6 8 10 12 14 16
```

- Creating a range and adding it to list
 - In this method we shall create a list outside the range object and then iterate over the range and then add it to list

```
In [3]: l1 = []
        r1 = range(4,18,2)
        for i in r1:
            l1.append(i)
        print(l1)
        print(r1)

[4, 6, 8, 10, 12, 14, 16]
range(4, 18, 2)
```

- Creating the range object and adding it to the list object using list()

```
In [4]: r1 = range(4,18,2)
        l2 = list(r1)
```

```
In [5]: l2
```

```
Out[5]: [4, 6, 8, 10, 12, 14, 16]
```

Lists

- Lists are the objects that are ordered sequentially
- Lists start from index 0
- Lists are iterable objects
- Lists can be iterated over using the for loop
- Lists can be sliced that is they can be indexed over
- Lists can be iterated
- Lists are mutable
- Addition and deletion of elements/values are possible in List.
- We represent lists using the [] - Square brackets.

```
In [6]: r3 = range(4,18,2)
        l3 = list(r3)
```

```
In [7]: l3
```

```
Out[7]: [4, 6, 8, 10, 12, 14, 16]
```

- Iterating over lists
 - Using for loop we can iterate over the list We create a range object and then create a list object. We iterate over the list object using the for loop

```
In [10]: r3 = range(4,18,2)
         l3 = list(r3)
         for i in l3 :
             if i > 34:
                 break
             doublei = i*2
```

```
if doublei not in l3:
    l3.append(doublei)
print(i, end=' ')
```

4 6 8 10 12 14 16 20 24 28 32

- Slicing the list - we use the ':' and '[]' to slice the list objects
- In the example below, we shall build the list using the range object

```
In [11]: slicList = list(range(15))
slicList[:]
```

Out[11]: [0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14]

- Slice the l4 list object using the indices from 0 to 5

```
In [12]: slicList[0:5]
```

Out[12]: [0, 1, 2, 3, 4]

- To reverse the list objects in the following format -
 - This will reverse the elements in the reverse format alternate numbers

```
In [18]: slicList[::-1]
```

Out[18]: [14, 13, 12, 11, 10, 9, 8, 7, 6, 5, 4, 3, 2, 1, 0]

```
In [19]: slicList[::-2]
```

Out[19]: [14, 12, 10, 8, 6, 4, 2, 0]

- Can also add step size for the list
 - Step value is how much needs to be added to the previous element to get the next elements in the list

```
In [22]: slicList[1:7:2]
```

Out[22]: [1, 3, 5]

- Slicing of String values in the list

```
In [13]: names = ['Abhilash', 'Bharat', 'Chandra', 'Dinesh', 'Elangovan', 'Freddy', 'Girish']
names[:]
```

Out[13]: ['Abhilash', 'Bharat', 'Chandra', 'Dinesh', 'Elangovan', 'Freddy', 'Girish']

- using the index on the names list - to get the values from 1st index and 2nd index

```
In [26]: names[1:3]
```

Out[26]: ['Bharat', 'Chandra']

```
In [27]: names[1:5]
```

```
Out[27]: ['Bharat', 'Chandra', 'Dinesh', 'Elangovan']
```

- Reversing the list

```
In [28]: names[::-1]
```

```
Out[28]: ['Girish', 'Freddy', 'Elangovan', 'Dinesh', 'Chandra', 'Bharat', 'Abhilash']
```

- Check the list now and we shall remove and retrieve the elements using pop
 - pop() returns the element and removes the element from the list

```
In [29]: names.pop()
```

```
Out[29]: 'Girish'
```

```
In [32]: ## As we see in the list below once 'girish' is popped, there is no 'girish' element at  
names
```

```
Out[32]: ['Abhilash', 'Bharat', 'Chandra', 'Dinesh', 'Elangovan', 'Freddy']
```

- find the length of the list using the len() function

```
In [33]: len(names)
```

```
Out[33]: 6
```

- remove() - Using the remove function on the list removes the element from the list
 - Lets say if we had two values then it removes only first occurrence from the list

```
In [34]: names.remove('Freddy')
```

```
In [35]: ## Check the names function and we see that Freddy is no longer available in the names l  
names
```

```
Out[35]: ['Abhilash', 'Bharat', 'Chandra', 'Dinesh', 'Elangovan']
```

- Let us add two values to the list and then apply remove -
 - Farhan is added twice using the append() function

```
In [36]: names.append('Farhan')  
names.append('Farhan')
```

```
In [38]: ## As we see there are two values with the name 'Farhan'  
names
```

```
Out[38]: ['Abhilash', 'Bharat', 'Chandra', 'Dinesh', 'Elangovan', 'Farhan', 'Farhan']
```

- use remove() on the names list and check the output

```
In [39]: names.remove('Farhan')
names ## There is only one value of 'Farhan' in the list
```

```
Out[39]: ['Abhilash', 'Bharat', 'Chandra', 'Dinesh', 'Elangovan', 'Farhan']
```

- extend() can add multiple elements to the list

```
In [14]: names.extend(['Giridhar', 'Hema', 'Jishnu'])
```

```
In [15]: ## Display the elements with the latest names added to the list
names
```

```
Out[15]: ['Abhilash',
          'Bharat',
          'Chandra',
          'Dinesh',
          'Elangovan',
          'Freddy',
          'Girish',
          'Giridhar',
          'Hema',
          'Jishnu']
```

- Reverse the original list using reverse() function on the list
 - reverse() function reverses the list and generates the output

```
In [16]: names.reverse()
```

```
In [17]: names # The list has been reversed and stores the values in the list in reverse order
```

```
Out[17]: ['Jishnu',
          'Hema',
          'Giridhar',
          'Girish',
          'Freddy',
          'Elangovan',
          'Dinesh',
          'Chandra',
          'Bharat',
          'Abhilash']
```

- clear() method is used to empty the lists

```
In [18]: names.clear()
```

```
In [19]: names ## In the above cell , clear() was used to clear the list and now we have no value
```

```
Out[19]: []
```

- Iterating over the lists using for loop

```
In [50]: ### Lets us add the friends to the names list
```

```
In [20]: names = ['Abhilash', 'Bharat', 'Chandra', 'Dinesh', 'Elangovan', 'Freddy', 'Girish']
```

```
In [21]: for friend in names:
          print(friend, end=',') ## We can print the value as show in this
```

- Exercise - Add names from the input prompt and store the values in the list

```
In [3]: frNames= []
while True:
    addName = input(' Would you like to add a name ? Type yes/y or no/n : ')
    addName = addName.lower()
    if addName == 'yes' or addName == 'y' :
        name = input('Enter the name of the friend : ')
        frNames.append(name)
    elif addName == 'no' or addName == 'n':
        print('No more names are added -- Good bye !!')
        print('The friends list are {}'.format(frNames))
        break
    else:
        print('Wrong Input -- Can accept only yes/y or no/n .. Exiting....')
        break
```

Would you like to add a name ? Type yes/y or no/n : What
Wrong Input -- Can accept only yes/y or no/n .. Exiting....

- Elements of the list can be sorted using sort() function

```
In [58]: frNames.sort()
```

```
In [60]: frNames
```

```
Out[60]: ['Bindu', 'Chandra', 'abhishek']
```

- getting the index of a 'Chandra' from the list using index()

```
In [62]: frNames.index('Chandra')
```

```
Out[62]: 1
```

- sum() function on the list object
- sum() function is used to calculate the sum of the iterable objects
- In the below example, we pass list to sum function
- len() function gives the length of the iterable or the list
- Average/mean can be computed using the sum() and len() function

```
In [3]: ## Lets build a list using 10,11,12,13,14,15,16 - The sum of all the elements in the lis
### in two ways - sum(intList) or using for loops
intList = [10,11,12,13,14,15,17]
print('Sum of the list of elements',sum(intList))
print(intList)
numOfEle = len(intList)
meanIntList = sum(intList)/numOfEle
print(meanIntList)
```

Sum of the list of elements 92
[10, 11, 12, 13, 14, 15, 17]
13.142857142857142

- sum of the elements using the for loop

```
In [64]: intList = 10,11,12,13,14,15,16
        slist = 0
        for i in intList:
            slist += i
        print(slist)
```

91

- list comprehensions are writing simple code in a single line

```
In [65]: ## Based on the range object lets find the square of each number
        y = [x**2 for x in range(5)]
```

```
In [66]: y
```

```
Out[66]: [0, 1, 4, 9, 16]
```

- Condition in the List Comprehension

```
In [67]: ## We can also include condition within the for comprehension
        y = [x**2 for x in range(10) if x%2 == 0 ]
        print(y)
```

```
[0, 4, 16, 36, 64]
```

- Condition with the string values/list

```
In [6]: ### return if only list contains letters starting with s
        names = ['sunday','super','semi-conductor','non-conductor','mango','apple']
        y = [x for x in names if x.startswith('s')]
```

```
In [7]: y
```

```
Out[7]: ['sunday', 'super', 'semi-conductor']
```

```
In [8]: del y[0]
```

```
In [9]: y
```

```

Tuples

- **Tuples** are immutable objects that can be represented in ()
 - We cannot add,modify or remove elements from Tuples
- Tuples can be accessed using indices
- Tuples are created by passing values to ()
- Tuples can iterated using for loop
- Tuple values can be assigned to multiple variables in a single line

```
In [12]: tup1 = (25,'Mango','Rajesh',40,25,24,25)
        tup1[1]
```

```
Out[12]: 'Mango'
```

```
In [13]: tup1[3]
```

```
Out[13]: 40
```

```
In [72]: ### Tuples can be iterated over using for loop  
for x in tup1:  
    print(x)
```

```
25  
Mango  
Rajesh  
40  
25  
24  
25
```

```
In [73]: ## Assigning a value to tuple shows error - tuple object does not support assignment  
tup1[0] = 35
```

```
{'Ravi', 'Kiran', 'Mahesh', 'Suraj', 'Mitra', 'Surya'}
{'kiran', 'Mahesh', 'Mitra'}
```

- Symmetric difference gives the elements that are not common as one single set.

```
In [22]: ## els.symmetric_difference(els2) gives the common elements between both the sets.
els.symmetric_difference(els2)
```

```
Out[22]: {'Kiran', 'Ravi', 'Suraj', 'Surya', 'kiran'}
```

- Comprehension for set - Similar to for comprehension for Set
 - return type is Set when set comprehension is performed

```
In [13]: listVal = {'Mahesh', 'Mahesh', 'Suraj', 'Ravi', 'Kiran', 'Surya'}
uniEle = set()
for name in listVal:
    name = 'Mr ' + name
    uniEle.add(name)
print(uniEle)
```

```
{'Mr Mahesh', 'Mr Suraj', 'Mr Ravi', 'Mr Surya', 'Mr Kiran'}
```

```
In [14]: listVal = {'Mahesh', 'Mahesh', 'Suraj', 'Ravi', 'Kiran', 'Surya'}
uniEle = {'Mr ' + x for x in listVal}
uniEle
```

```
Out[14]: {'Mr Kiran', 'Mr Mahesh', 'Mr Ravi', 'Mr Suraj', 'Mr Surya'}
```

- list can be created using [] or list()
- tuple can be created using () or tuple()
- Dictionary can be created using {} or dict()
- sets can be created using {} or set()

Why are we using data structures

- We want to store multiple values
- List : Ordered set of values and we want to iterate over the values
 - Index based accessing
- Set : Store only unique elements then we shall go for set or we do not want to allow duplicate elements
- Tuple : We do not want to modify the values while storage and no modification of values
- Dictionary : We want identifiers for values or key/value pairs

- **Dictionary in Python** - Dictionaries in Python are basically key,value pairs.
 - In a dictionary, key can be any unique object
 - Keys are unique and non-duplicated
 - Values can be duplicated
 - Dictionaries can be constructed using the dict() or {}
- Create Dictionary using the dict() keyword

```
In [16]: idName = dict()
idName[101] = 'Suraj'
idName[102] = 'Mahesh'
idName[103] = 'Surya'
idName[104] = 'Ravi'
idName[105] = 'Kiran'
idName[106] = 'Mitra'
idName[107] = 'Mahesh B'
print(idName)

{101: 'Suraj', 102: 'Mahesh', 103: 'Surya', 104: 'Ravi', 105: 'Kiran', 106: 'Mitra', 107: 'Mahesh B'}
```

```
In [17]: ### Another way of creating the dictionary is the following
idName = {101: 'Suraj', 102: 'Mahesh', 103: 'Surya',
          104: 'Ravi', 105: 'Kiran', 106: 'Mitra',
          109: 'Akhilesh'}
print(idName)

{101: 'Suraj', 102: 'Mahesh', 103: 'Surya', 104: 'Ravi', 105: 'Kiran', 106: 'Mitra', 109: 'Akhilesh'}
```

- Retrieve the value in the dictionary using key

```
In [32]: ### The dictionary name and the id can be passed to get the value - idName[101]
### dictionaryName[keyValue]
idName[101]
```

```
Out[32]: 'Suraj'
```

- Check if the key is in the dictionary

```
In [33]: ### Check if a particular key is available in the dictionary - 101 in idName
101 in idName
```

```
Out[33]: True
```

```
In [18]: ### Check if a particular key is not available in the dictionary - 109 not in idName
print(109 not in idName)
print(110 in idName)
```

```
False
False
```

- iterate over the dictionary using keys()

```
In [36]: idName.keys()
```

```
Out[36]: dict_keys([101, 102, 103, 104, 105, 106, 109])
```

```
In [35]: ### We can iterate over the dictionary using the keys() function on the dictionary.
for k in idName.keys():
    print(f'Key is {k}')

Key is 101
Key is 102
Key is 103
Key is 104
Key is 105
Key is 106
Key is 109
```

- Values for the dictionary using values()

```
In [139... for v in idName.values():
    print(f'value is {v}')

value is Suraj
value is Mahesh
value is Surya
value is Ravi
value is Kiran
value is Mitra
```

- iterate over a dictionary using items()

```
In [22]: for key,value in idName.items():
    print(f'Id is {key}, Name is {value}')
    print('Id is {} , Name is {}'.format(key,value))

Id is 101, Name is Suraj
101 Suraj
Id is 102, Name is Mahesh
102 Mahesh
Id is 103, Name is Surya
103 Surya
Id is 104, Name is Ravi
104 Ravi
Id is 105, Name is Kiran
105 Kiran
Id is 106, Name is Mitra
106 Mitra
Id is 109, Name is Akhilesh
109 Akhilesh
```

- Iterate over a dictionary using the dictionary object

```
In [141... ### Using the dictionary object only the dictionary is used
for keyVal in idName:
    print(keyVal)

101
102
103
104
105
106
```

- Delete a key in the dictionary using the del keyword

```
In [142... ## Delete the key value pair using the idName[key]  
del idName[101]
```

```
In [143... idName
```

```
Out[143]: {102: 'Mahesh', 103: 'Surya', 104: 'Ravi', 105: 'Kiran', 106: 'Mitra'}
```

- To get a value from the dictionary using the get() function or the []

```
In [144... idName[102]
```

```
Out[144]: 'Mahesh'
```

```
In [145... idName.get(102)
```

```
Out[145]: 'Mahesh'
```

- If the key is not in the dictionary using the get() method we can use the default value

```
In [37]: ### Lets say we dont have the key/value pair in the dictionary it returns a key erro  
idName[110]
```

```
-----  
KeyError                                Traceback (most recent call last)  
Cell In[37], line 2  
      1 ### Lets say we dont have the key/value pair in the dictionary it returns a key  
        erro  
----> 2 idName[110]  
KeyError: 110
```

```
In [147... # If the key is available then it returns the value  
idName.get(102,"Value is Not there")
```

```
Out[147]: 'Mahesh'
```

```
In [39]: idName.get(110,"Key/Value is Not there")
```

```
Out[39]: 'Key/Value is Not there'
```

```
In [149... ### To get the keys in the reversed order we can use reversed on the dictionary
```

```
In [40]: for i in reversed(idName):  
        print(i)
```

```
109  
106  
105  
104  
103  
102  
101
```

```
In [151... ## Collecting the dictionary keys as list - list(idName)  
list(idName)
```

```
Out[151]: [102, 103, 104, 105, 106]
```

- To remove one key,value pair from the dictionary - using popitem()

```
In [41]: ## idName.popitem() will remove one key value pair from the dictionary
idName.popitem()
```

```
Out[41]: (109, 'Akhilesh')
```

- To remove one key at a time from the dictionary - using pop()

```
In [42]: ### ## idName.pop(key) will pop one key value pair for the given key from the dictionary
idName.pop(104)
```

```
Out[42]: 'Ravi'
```

```
In [44]: ### If the key is not available in the dictionary, pop() shall given an error on the dic
idName.pop(105)
